Теплофизические свойства воды и пара в диапазоне температур 0...229 °C и давлений 0,1...5,0 МПа: Справочное пособие для энергетических расчетов. – К.: Институт электродинамики НАН Украины, 2012. – 115 с.

Приведены таблицы значений плотности и удельной энталпии воды и пара в диапазоне температур 0...229 °C и давлений 0,1...5,0 МПа, а также табличные зависимости для определения состояния насыщения как при заданной температуре, так и при заданном давлении. Вычисления произведены в соответствии с рекомендациями Международной ассоциации по свойствам воды и водяного пара для применения в промышленных расчетах. Приведены все уравнения и контрольные значения, которые были использованы при составлении и проверке таблиц.

Справочное пособие предназначено для работников проектных организаций и для инженерно-технического персонала, занимающегося энергетическими расчетами и метрологическим обеспечением учета тепловой энергии в системах и установках, где в качестве теплоносителя применяется вода и пар. Пособие может быть полезно также для студентов соответствующих специальностей.

Введение

Таблицы, приведенные в справочном пособии для энергетических расчетов, предназначены для вычисления тепловой энергии в системах теплоснабжения и контроля качества работы вычислителей тепловой энергии в приборах и системах ее учета. Для составления таблиц термодинамических свойств воды использованы основные уравнения Международной системы уравнений 1997 г. для термодинамических свойств воды и водяного пара, составленные для промышленных расчетов [4], далее называемые Формуляцией IF-97.

Таблицы отличаются от уже существующих [1, 2] повышенной разрядностью приведенных данных и уменьшенным шагом сетки параметров (для упрощения построения и проверки технических аппроксимаций, облегчения интерполяционных вычислений). Разрядность данных и шаг сетки выбраны по аналогии с известными таблицами [3], которые к настоящему времени упразднены, поскольку принята новая Международная температурная шкала МТШ-90 [5]. Столь высокая разрядность данных необходима для точного вычисления тепловой энергии при малых значениях перепада температур и давлений на объектах теплоснабжения. Диапазон изменения значений температуры в таблицах ограничен значениями 0...229 °C, а давления – 0,1...5,0 МПа, то есть охватывает область жидкого состояния воды и перегретого пара. Диапазон допустимых температур для соответствующих уравнений Формуляции IF-97 составляет 0...450 °C, а диапазон допустимых давлений – 0...100 МПа, причем, 0 °C соответствует 273,15 К.

Линия насыщения

Область жидкого состояния воды ограничена линией насыщения – кипения воды. Эта линия описывается неявным квадратным уравнением, которое может быть решено как относительно давления насыщения p_S , так и относительно температуры насыщения T_S . Это уравнение имеет следующий вид:

$$\beta^2 \cdot \vartheta^2 + n_1 \cdot \beta^2 \cdot \vartheta + n_2 \cdot \beta^2 + n_3 \cdot \beta \cdot \vartheta^2 + n_4 \cdot \beta \cdot \vartheta + n_5 \cdot \beta + n_6 \cdot \vartheta^2 + n_7 \cdot \vartheta + n_8 = 0, \quad (1)$$

где $\beta = (p_S / p^*)^{1/4}$ (1a)

$$\text{и } \vartheta = \frac{T_S}{T^*} + \frac{n_9}{(T_S/T^*) - n_{10}}, \quad (16)$$

причем $p^* = 1$ МПа и $T^* = 1$ К – для коэффициентов $n_1 \dots n_{10}$ согласно табл. 1.

Решение уравнения (1) относительно давления насыщения p_S :

$$\frac{p_s}{p^*} = \left[\frac{2 \cdot C}{-B + (B^2 - 4 \cdot A \cdot C)^{1/2}} \right]^4, \quad (2)$$

если $p^* = 1$ МПа и

$$A = \vartheta^2 + n_1 \cdot \vartheta + n_2; \quad B = n_3 \cdot \vartheta^2 + n_4 \cdot \vartheta + n_5; \quad C = n_6 \cdot \vartheta^2 + n_7 \cdot \vartheta + n_8,$$

где ϑ соответствует уравнению (1б), а коэффициенты $n_1 \dots n_{10}$ – табл. 1.

Уравнение (2) действительно вдоль линии насыщения водяного пара от тройной точки воды до критической температуры, и поэтому может быть применено для температурного диапазона $273,15 \text{ K} \leq T \leq 647,096 \text{ K}$.

Формуляция IF-97 предоставляет три контрольные точки для проверки правильности вычислений по формуле (2):

$$T = 300 \text{ K}, \quad p = 0,353\,658\,941 \times 10^{-2} \text{ МПа}$$

$$T = 500 \text{ K}, \quad p = 0,263\,889\,776 \times 10^1 \text{ МПа}$$

$$T = 600 \text{ K}, \quad p = 0,123\,443\,146 \times 10^2 \text{ МПа}$$

Решение уравнения (1) относительно температуры насыщения T_s :

$$\frac{T_s}{T^*} = \frac{n_{10} + D - \left[(n_{10} + D)^2 - 4 \cdot (n_9 + n_{10} \cdot D) \right]^{1/2}}{2}, \quad (3)$$

если $T^* = 1 \text{ K}$ и

$$D = \frac{2 \cdot G}{-F - (F^2 - 4 \cdot E \cdot G)^{1/2}}$$

$$\text{при } E = \beta^2 + n_3 \cdot \beta + n_6; \quad F = n_1 \cdot \beta^2 + n_4 \cdot \beta + n_7; \quad G = n_2 \cdot \beta^2 + n_5 \cdot \beta + n_8,$$

где β соответствует уравнению (1а), а коэффициенты $n_1 \dots n_{10}$ – табл. 1.

Уравнение (3) имеет тот же диапазон обоснованности, что и уравнение (2). Это означает, что оно действительно для линии насыщения водяного пара в диапазоне давлений $611,213 \text{ Па} \leq p \leq 22,064 \text{ МПа}$. Значение давления $611,213 \text{ Па}$ соответствует значению температуры, экстраполированной до $273,15 \text{ K}$, то есть, до 0°C .

Область жидкого состояния воды

Основным уравнением в области жидкого состояния воды является уравнение для удельной энергии Гиббса как функции приведенных (безразмерных) значений давления и температуры:

$$\frac{g(p,T)}{R \cdot T} = \gamma(\pi, \tau) = \sum_{i=1}^{34} A_i \cdot (7,1 - \pi)^{I_i} \cdot (\tau - 1,222)^{J_i}, \quad (4)$$

где $\pi = p / p^*$; $\tau = T^* / T$; $p^* = 16,53$ МПа; $T^* = 1386$ К; удельная газовая постоянная $R = 0,461526$ кДж / (кг·К).

Значения коэффициентов A_i и показателей степени I_i и J_i для этого уравнения приведены в табл. 2.

Таблица 2. Значения коэффициентов в формуле (4)

Все термодинамические параметры воды могут быть получены из уравнения (4) с помощью дифференциальных уравнений термодинамики. В частности, для удельного объема v (π , τ) справедливо выражение

$$v(\pi, \tau) = \frac{R \cdot T}{p} \cdot \pi \cdot \frac{\partial \gamma}{\partial \pi}, \quad (5)$$

для плотности воды $\rho(\pi, \tau)$ –

$$\rho(\pi, \tau) = \frac{1}{v(\pi, \tau)}, \quad (6)$$

для удельной энталпии $h(p, T)$ –

$$h(\pi, \tau) = R \cdot T \cdot \tau \cdot \frac{\partial \gamma}{\partial \tau} = R \cdot T^* \cdot \frac{\partial \gamma}{\partial \tau}. \quad (7)$$

Частные производные в выражениях (5) и (7) могут быть получены численным дифференцированием функции (4) по соответствующему параметру, так как эта функция является принципиально гладкой для жидкой фазы воды. Но в соответствии с Формуляцией IF-97 допустимо использовать аналитические выражения для частных производных, полученные прямым дифференцированием ряда, используемого в выражении (4):

$$\frac{\partial \gamma}{\partial \pi} = \sum_{i=1}^{34} A_i \cdot (-I_i) \cdot (7,1-\pi)^{(I_i-1)} \cdot (\tau-1,222)^{J_i}; \quad (8)$$

$$\frac{\partial \gamma}{\partial \tau} = \sum_{i=1}^{34} A_i \cdot J_i \cdot (7,1-\pi)^{I_i} \cdot (\tau-1,222)^{(J_i-1)}. \quad (9)$$

Область перегретого пара

Основным в области перегретого пара является уравнение для удельной энергии Гиббса как функция приведенных (безразмерных) значений давления и температуры. В отличие от уравнения для жидкого состояния воды уравнение для перегретого пара (10) состоит из суммы двух компонентов: выражения для идеального газа (11) и поправки на реальные свойства водяного пара (12):

$$\frac{g(p, T)}{R \cdot T} = \gamma(\pi, \tau) = \gamma^0(\pi, \tau) + \gamma^r(\pi, \tau); \quad (10)$$

$$\gamma^0(\pi, \tau) = \ln \pi + \sum_{i=1}^9 n_i^0 \cdot \tau^{J_i^0}; \quad (11)$$

$$\gamma^r(\pi, \tau) = \sum_{i=1}^{43} n_i \cdot \pi^{I_i} \cdot (\tau-0.5)^{J_i}, \quad (12)$$

где $\pi = p / p^*$; $\tau = T^* / T$; $p^* = 1,0$ МПа; $T^* = 540$ К; удельная газовая постоянная $R = 0,461526$ кДж / (кг·К).

Значения коэффициентов n_i^0 и показателей степени J_i^0 для уравнения (11) приведены в табл. 3, а значения коэффициентов n_i и показателей степени I_i и J_i для уравнения (12) – в табл. 4.

22	6	35	$-0,23895741934104 \times 10^2$				

Выражения для интересующих нас параметров перегретого водяного пара могут быть получены из уравнения (10) с помощью уже известных зависимостей (5)...(7) соответственно. Частные производные в выражениях (5) и (7) могут быть получены численным дифференцированием функции (12) по соответствующему параметру. Аналитические выражения для частных производных, полученные прямым дифференцированием рядов, используемых в выражениях (11) и (12), можно записать так:

$$\frac{\partial \gamma}{\partial \pi} = \frac{\partial \gamma^0}{\partial \pi} + \frac{\partial \gamma^r}{\partial \pi} = \frac{1}{\pi} + \sum_{i=1}^{43} n_i \cdot I_i \cdot \pi^{(I_i-1)} \cdot (\tau - 0,5)^{J_i}; \quad (13)$$

$$\frac{\partial \gamma}{\partial \tau} = \frac{\partial \gamma^0}{\partial \tau} + \frac{\partial \gamma^r}{\partial \tau} = \sum_{i=1}^9 n_i^0 \cdot J_i^0 \cdot \tau^{J_i^0-1} + \sum_{i=1}^{43} n_i \cdot \pi^{I_i} \cdot J_i \cdot (\tau - 0,5)^{J_i-1}. \quad (14)$$

Таким образом, окончательные выражения для вычисления удельного объема перегретого пара принимают следующий вид:

$$v(\pi, \tau) = \frac{R \cdot T}{p} \cdot \pi \cdot \frac{\partial \gamma}{\partial \pi} = \frac{R \cdot T}{p} \cdot \left[1 + \sum_{i=1}^{43} n_i \cdot I_i \cdot \pi^{I_i} \cdot (\tau - 0,5)^{J_i} \right]. \quad (15)$$

Для плотности:

$$\rho(\pi, \tau) = \frac{1}{v(\pi, \tau)}. \quad (16)$$

Для удельной энталпии:

$$h(\pi, \tau) = R \cdot T \cdot \tau \cdot \frac{\partial \gamma}{\partial \tau} = R \cdot T^* \cdot \left[\sum_{i=1}^9 n_i^0 \cdot J_i^0 \cdot \tau^{J_i^0-1} + \sum_{i=1}^{43} n_i \cdot \pi^{I_i} \cdot J_i \cdot (\tau - 0,5)^{J_i-1} \right]. \quad (17)$$

Результаты вычислений

В приложении А представлены результаты вычисления линии насыщения как функции давления от температуры в соответствии с выражением (2). Формуляция IF-97 дает оценку погрешности вычисления давления $\pm 0,03\%$ для температур до $100\text{ }^{\circ}\text{C}$ и $\pm 0,05\%$ для более высоких температур.

В приложении Б представлены результаты вычисления линии насыщения как функции температуры от давления в соответствии с выражением (3).

В приложении В представлены результаты вычисления плотности воды по выражению (6) с применением ряда (8) и пара по выражению (16). Формуляция IF-97 дает оценку погрешности приведенных данных $\pm 0,003\%$ для жидкой фазы при температурах до $150\text{ }^{\circ}\text{C}$ и $\pm 0,015\%$ для более высоких температур, а для пара – до $\pm 0,05\%$.

В приложении Г представлены результаты вычисления удельной энталпии воды по выражению (7) с применением ряда (9) и пара по выражению (17). Абсолютные погрешности вычисления удельной энталпии,

рассчитанной по Формуляции IF-97, приведены в работе [1]. Однако эти оценки погрешности мало полезны для энергетических расчетов, когда необходимо вычислить разницу энергии при небольшом изменении температуры. Оценку относительной погрешности таких разностных вычислений можно произвести по аналогии с данными для удельной изобарной теплоемкости [4]: $\pm 0,2\%$ для жидкой фазы и до $\pm 0,3\%$ для пара.
